Golf Course Toxic Hazard Awareness

Golf course maintenance and green staff use several different chemical herbicides and fertilizers on the greens, fairways and T's to ensure the grass and course remains in pristine condition. However, many of these sprays and mixtures contain harmful ingredients many of which cause irritation of the skin, eyes and internal organ damage through short and long term exposure. These effects can also apply to the golfers using the course, particularly when the spraying and spreading of these mixtures are taking place.

CBRN Solutions UK, an experienced company in CBRN matters have identified a number of shortfalls in golf clubs' awareness of the potential danger posed to their ground staff and golfing members and can offer advice, training and Personal Protective Equipment (PPE) to management and ground staff to mitigate against these hazards. Additionally, many clubs do not have written processes and procedures in place for conducting herbicide and fertilizer spraying and spreading techniques. It is becoming more common for club health and safety and insurance purposes to ensure these measures are in place and auditable.

Some of the important shortfalls are:

- **Greenkeeper staff unaware of the long term effects of toxic hazard exposure.**
- **Lack of correct PPE**
- **Cross contamination**
- **Correct storage requirements for spraying and Spreading materials.**
- **Fire and combustion risk**
- **Management responsibilities and liabilities**

CBRN Solutions UK offers a **complete Turnkey solution**, incorporating:

- **Review of current PPE, processes and procedures.**
- **Half day Toxic Hazard Awareness training course.**
- **Supply of PPE**
- **Quality assured products**
